How this task works

Workflow

Review instructions before beginning annotation.

Your job is to provide a qualitative assessment of each agent's rollout. The task, rollouts and completeness check have already been done. A detailed walkthrough is available in the project guide here.

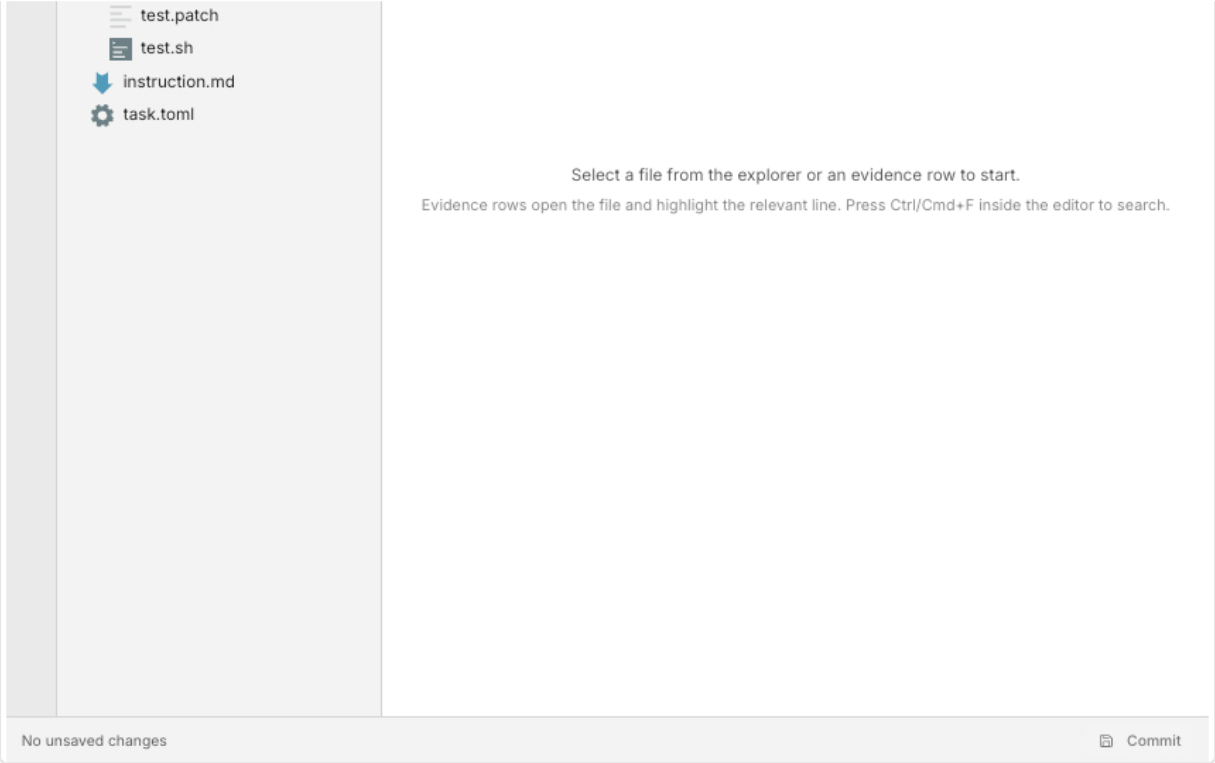
1. Before starting, make sure you spot check the task and trajectories. There should be two trajectories and corresponding solution patches.
2. Develop 10-20 PASS/FAIL rubric criteria based on the task requirements.
3. Score each trajectory on Dimensions 1-9 and the rubric.
4. Write a comparison of the two models' performance and decide which was better.

Task

Task repository, instructions, configuration, and reference solution assets.

Task bundle

Inspect instruction.md, task.toml, test specifications, and solution assets.



Task type

Full rollout evidence

Full transcripts and patches for Trajectory A and Trajectory B bound to their run IDs.

Agent Trajectories

Trajectory Viewer

Inspect prompts, tool execution logs, and full diff outputs for each trajectory.

Model A Model B

Model B completed 4271.7s

PROMPT

System

You are an agent that completes tasks independently.

FINAL ANSWER

I have implemented server-side keyset continuation pagination across both synchronous (`ListRequestHandler`) and asynchronous (`ListRequestHandlerAsync`) list request handlers in Serenity.

Summary of Changes

1. **Request & Response Models (`src/services/Models/ListRequest.cs`, `src/services/Models/ListResponse.cs`, TypeScript & CodeGen typings)**
   - Added optional `string? PageToken { get; set; }` to `ListRequest` and optional `string? NextPageToken { get; set; }` to `ListResponse<T>` (m

Payload:

```
Please solve this issue: Serenity's list request handlers only support Skip/Take offset pagination. Add server-side keyset continuation
pagination across both synchronous and asynchronous list request handlers.

`ListRequest` gains an optional string property named `PageToken`, and `ListResponse<T>` gains an optional string property named
```

`NextPageToken`. When set, the handler resumes listing strictly after the boundary row represented by the token; when null or absent, it returns the first page.

Keyset pagination requires `Take > 0`, `Skip == 0`, `DistinctFields == null`, and an entity implementing `IIdRow`. On a first-page request, failing any of these leaves keyset pagination inactive (the next page token remains null). When a token is provided, failing any precondition—or supplying a token that is malformed, corrupted, or replayed against a different effective sort order, `Criteria`, `EqualityFilter`, `ContainsText`, `ContainsField`, or `IncludeDeleted`—must throw `ValidationError`.

Effective sort order for keyset pagination uses the request sort (or the handler's native sort order when empty), appending the entity's primary key ID field as an ascending tiebreaker if not already present. On a first-page request without a token, existing handler sort ordering is preserved verbatim.

Boundary sort values extracted from the last returned entity must round-trip through the token preserving type and precision across `DateTime`, `DateTimeOffset`, `Guid`, `decimal`, floating-point, boolean, enum, string, and null values. Sort and tiebreaker columns must be selected so values can be extracted even when restricted by `ColumnSelection.KeyOnly` or `ExcludeColumns`. Mapped field expressions (such as localization rewrites) must be used consistently between ordering and seek filtering.

0.1 reasoning I've gone through the core models and handler mechanics. A few findings... +0s 71m 21s

I've gone through the core models and handler mechanics. A few findings that shape how we design the continuation pagination:

- **Sort Precedence**: `ApplySort` loops backwards through sort items and calls `query.OrderByFirst`, prepending them ahead of the primary key tiebreaker added earlier by `ApplyKeyOrder`.
- **Field Rewrites**: `MapFieldExpression` intercepts and maps columns during selection and criteria building. We'll need to ensure the exact same mapped expressions apply to the seek filter predicates.
- **Dialects**: Serenity targets six database backends (`Firebird`, `MySql`, `Oracle`, `Postgres`, `Sqlite`, and `SqlServer`), each with

distinct default NULL ordering rules.

Next, I'll check `SqlQuery_ToString.cs` and grep for any `NULLS` sorting references across the codebase to see how `SqlQuery` formats order clauses for different dialects.

Payload:

```

0.1 reasoning I dug into `SqlQuery_ToString.cs` and found a neat structural detail: Sereni... +0s 71m 21s

I dug into `SqlQuery_ToString.cs` and found a neat structural detail: Serenity already uses an internal `extraWhere` hook that appends conditions strictly to the data `SELECT` while keeping the `SELECT count(*)` query completely separate. This lets us inject the keyset seek predicate without shrinking `TotalCount` across subsequent pages.

I also checked the entity field types and caught two round-trip details to be mindful of:

- `DateTimeOffsetField.ConvertValue` drops the timezone offset, so we need a lossless binary serialization for the token envelope.
- `EnumField` returns an underlying `int` via `AsObject`, so we must check `IEnumTypeField` to reconstruct the exact runtime enum type for parameterized seek queries.

I am moving into the implementation phase. First, I'll add the `PageToken` and `NextPageToken` properties to the C# models, update the TypeScript interfaces, and rebuild `corelib` to sync the generated typings.

Payload:

```

0.1 reasoning I've finished writing the changes across all layers: +0s 71m 21s

I've finished writing the changes across all layers:

- **Models & Typings**: Added `PageToken` and `NextPageToken` to `ListRequest`/`ListResponse<T>`, updated the TypeScript definitions, and rebuilt the core library bundles.
- **SQL Query Engine**: Added the internal `seekFilter` hook to `SqlQuery` to isolate keyset predicates from the `SELECT count(*)` query, keeping `TotalCount` stable across pages.
- **Token Envelope**: Created `KeysetPaginationHelper.cs` to handle binary serialization (preserving exact precision and runtime types for offsets, enums, decimals, and dates), request fingerprinting, and SHA-256 integrity checks.
- **Handlers**: Wired up precondition validation, effective sort resolution, column selection overrides, and probe row trimming into both `ListRequestHandler` and `ListRequestHandlerAsync`.

Next, I'll build the project with full analyzers and run the existing test suite to ensure no regressions were introduced before I build out dedicated keyset pagination tests.

Payload:

```

Hit a couple of quick snags in the simulated mock suite: `MockDbDataReader` threw a parameter count mismatch when reflecting on the dictionaries, and `AutoQuotedIdentifiers` wrapped our column check in brackets (`T0.[Category] IS NOT NULL`). While I tweak those helpers, let's check how the live SQLite integration suite handles the real database queries.

Payload:

```

Got 23 out of 29 tests green now, and the remaining 6 failures point to a few quirks in my simulated SQL test harness:

- Function arguments like `COALESCE(...)` broke my simple comma-splitting helper on `ORDER BY`.
- `AutoQuotedIdentifiers` wrapped the `ORDER BY` identifiers in brackets.
- Non-SQL Server dialects (Postgres, Oracle, Firebird) quote column aliases in ways the TSQL mock reader parser doesn't expect.

I'll adjust the mock test helpers to handle top-level comma splitting and alias matching properly, then re-run the suite.

0.1 reasoning That did the trick—all 29 simulated tests are green across all six dialects. +0s 71m 21s

That did the trick—all 29 simulated tests are green across all six dialects.

Before a full repo build and test sweep, I spotted a subtle edge case with localized or mapped fields. If a client fetches page 1 under `Localize = "en"` and replays that token against `Localize = "tr"`, the effective SQL sort expression changes even though the column names are identical. I'm going to move the request fingerprint generation slightly further down the lifecycle, right after `PrepareQuery`, so we capture the exact resolved SQL expression and reject cross-language replays before hitting the database.

Payload:

```

0.1 reasoning I have implemented server-side keyset continuation pagination across bot... +0.001s 71m 21s

I have implemented server-side keyset continuation pagination across both synchronous (`ListRequestHandler`) and asynchronous (`ListRequestHandlerAsync`) list request handlers in Serenity.

Summary of Changes

Request & Response Models (`src/services/Models/ListRequest.cs`, `src/services/Models/ListResponse.cs`, TypeScript & CodeGen typings)

- Added optional `string? PageToken { get; set; }` to `ListRequest` and optional `string? NextPageToken { get; set; }` to `ListResponse<T>` (mirrored in `packages/corelib` and `BuiltinTSTypes.gen.cs`).

Token Encoding, Validation & Dialect-Aware Seek Predicate Generation (`src/services/RequestHandlers/List/KeysetPaginationHelper.cs`)

- Encodes continuation tokens as unpadded RFC 4648 Section 5 URL-safe Base64URL opaque strings protected by a SHA-256 integrity tag and a canonical SHA-256 request fingerprint covering entity row type, canonical effective sort columns/expressions, `Criteria`, `EqualityFilter`, `ContainsText`, `ContainsField`, and `IncludeDeleted`.
- Preserves runtime types and full bit precision across `DateTime` (100ns `Ticks` + `DateTimeKind`), `DateTimeOffset` (`Ticks` + `Offset`), `Guid`, `decimal` (all 128 bits including scale), `double`/`float` (IEEE-754 bits), `bool`, `Enum` (underlying `IEnumTypeField` / `EnumField<T>` type restoration), integer types, `string`, and `null`.

- Builds parameterized multi-column lexicographic seek predicates matching dialect-specific NULL ordering across both `ASC` and `DESC` directions for NULLS-first-in-ASC dialects (`SqlServer`, `MySql`, `Sqlite`) and NULLS-last-in-ASC dialects (`Postgres`, `Oracle`, `Firebird`), without inlining literal values.

Synchronous & Asynchronous List Handlers & SQL Count Preservation (`ListRequestHandlerBase.cs`, `ListRequestHandler.cs`, `ListRequestHandlerAsync.cs`, `SqlQuery*.cs`)

- Enforces keyset preconditions (`Take > 0`, `Skip == 0`, `DistinctFields == null`, `Row is IIdRow`): leaves keyset pagination inactive on first-page requests when unmet (`NextPageToken == null`), and throws `ValidationError` when `PageToken` is provided and any precondition fails or the token is malformed, corrupted, or replayed against mismatched sort/filter parameters.
- Preserves existing handler sort ordering verbatim on first-page requests without a token, while resolving the effective sort order (`Request.Sort` or `GetNativeSort()`, plus the primary key `IdField` ascending if not already present) and using mapped field expressions (`MapFieldExpression` / `IListMapFieldExpressionBehavior`) consistently across column selection, ordering, and seek filtering.
- Ensures sort and tiebreaker columns are selected even when restricted by `ColumnSelection.KeyOnly`, `ColumnSelection.None`, or `ExcludeColumns`.
- Over-fetches `Take + 1` rows to detect subsequent pages, strips the probe row before exposing `Response.Entities`, preserves `Response.Take == request.Take`, keeps `Response.Skip == 0` when paging with a token, and keeps `TotalCount` calculation semantics unchanged across pages.

Verification (`tests/Serenity.Net.Tests/.../ListRequestHandlerKeysetPaginationTests.cs`, `serene/tests/Serene.Tests/Services/ListKeysetPaginationSqliteTests.cs`)

- Verified with unit tests across all 6 SQL dialects (`SqlServer`, `MySql`, `Sqlite`, `Postgres`, `Oracle`, `Firebird`) and live end-to-end SQLite integration tests across sync and async handlers; all 7,057 tests in `Serenity.Net.Tests`, 671 tests in `Serenity.Net.CodeGenerator.Tests`, 343 tests in `Serene.Tests`, and TypeScript tests pass with zero warnings or errors.

Payload:

```

```
+ # List continuation pagination
+
+ Synchronous and asynchronous list handlers return `NextPageToken` when a request
+ has `Take > 0`, `Skip == 0`, no `DistinctFields` (including an empty array), an
+ `IIdRow` entity, and more matching rows. Send that token as `PageToken` to fetch
+ the next page. Stop when `NextPageToken` is null. A missing or null `PageToken`
+ starts a new listing. Ordinary offset and distinct requests continue to work,
+ but do not return continuation tokens.
+
+ ```json
+ { "Take": 50, "Sort": ["Name"], "ExcludeTotalCount": true }
+ ```
+
+ For the next page, repeat the request with `"PageToken": "<NextPageToken>"`.
+ Keep the sort, criteria, equality filters, quick-search text and field, and
+ `IncludeDeleted` unchanged. The page size and column selection may change.
+ Invalid, altered, or incompatible tokens produce `ValidationError` with code
+ `InvalidPageToken`. Tokens are opaque: clients should not parse or modify them.
+
+ Continuation ordering uses the requested sort, or the handler's native sort,
+ with the ID ascending as a unique tiebreaker unless already included. The initial
+ request retains the handler's existing ordering. Required sort and ID fields
+ are selected even with `KeyOnly` or column exclusions; field read permissions
+ are still enforced. A sort requiring an unreadable field disables continuation
+ on the initial request and rejects a continuation request.
+
+ Handlers fetch at most one extra row to detect another page. That probe is not
+ processed or returned. `Take` still reports the requested page size, `Skip`
+ remains zero, and `TotalCount` continues to count all matching rows rather than
+ only rows after the boundary. `ExcludeTotalCount` retains its existing meaning.
+
+ Tokens use authenticated encryption and preserve boundary value types and
+ precision. The current token key is process-scoped: application restarts
+ invalidate outstanding tokens, and multi-worker deployments need worker
+ affinity for a listing. A client receiving an invalid-token error can restart
+ from the first page. Continuations are not database snapshots; concurrent
+ changes to a row's sort values can move it across the boundary.
```

Rubric Table

Rubric

Write 10 to 20 criteria before recording rubric answers. Record A and B PASS or FAIL with evidence in the table. PASS always indicates compliant behavior.

Google Sheets | Open in New Tab | + Add Rubric Item

World Rubric

Criteria that apply to every task in this world

Index	Verifier Type	Depends on
1	Lighthouse Overall Result (all-or-nothing task score) </> Programmatic	

Task Rubric

Criteria specific to this task

Structured | Spreadsheet

✓ All changes saved | Columns

Add a rubric item, then paste rows from a spreadsheet to bulk-fill.

+ Add rubric item | ↑↓←→ move | ⇧+arrows select range | Enter / type to edit | ⌘C / ⌘V copy/paste | Del clear | Click row #/header to select a row/column | Drag the row handle to reorder

Deliverable AutoQC

Run annotation AutoQC and resolve blocking findings before submitting.

Rubric AutoQC

Run these additional rubric checks and resolve blocking findings before proceeding.
